1.0 INTRODUCTION

This report presents the findings of a hydrogeologic investigation of the Cabin Bar Ranch located at 610 South Highway 395 in Olancha, California (**Figure 1**). The Cabin Bar Ranch (site) consists of 420 contiguous acres located along Highway 395 and is situated between the Sierra Nevada Mountain Range to the west and the dry Owens Lake to the east (**Figure 1**). CGR currently operates a bottled water facility immediately south of the proposed project site at 1210 South Highway 395. CGR is proposing to expand the current bottling operations onto the site. The proposed expansion project includes the construction of a new water bottling facility and development of the shallow groundwater beneath the site as a bottled spring water source. This hydrogeologic investigation was conducted in general accordance with Geosyntec Consultants, Inc (Geosyntec) proposals dated March 15, 2010, May 5, 2010, and September 2, 2010.

This report includes a review of hydrogeology and geology of the site including the details of the installation and testing of three test wells. This report has been organized as follows:

- Section 1. – *Introduction*.
- Section 2.0. – *General Site Information and Well Information*. This section includes a general description of the site location, site topography and site features such as creeks, structures, and wells.
- Section 3.0 – *Regional Geology and Hydrogeology*. This section includes a description of the regional hydrogeology including regional watershed information.
- Section 4.0. – *Previous Hydrogeologic Site Studies*. A summary of the previous investigations is presented.
- Section 5.0. – *Drilling and Investigation Methodology*. Procedural information on drilling and well installation, flume installation, piezometer installation, aquifer testing, and water sampling is presented.
- Section 6.0. – *Investigative Results.* This section presents the results of the drilling, groundwater level gauging, aquifer testing, flume/spring flow gauging and water sample analyses. A description of the site geology including presentation of interpretive cross-sections is also presented.
- Section 7.0. – *Hydrogeologic Site Conceptual Model*. A discussion of the site hydrogeology and aquifer system is presented including a development of a Hydrogeologic Site Conceptual Model.

- Section 8.0. – *Groundwater Flow Modeling*. The methodology and results of groundwater modeling is presented in this section. The model predicts long-term effects on groundwater levels and spring flow.
- Section 9.0 – *Salient Findings and Conclusions*. This section provides a summary of the salient information and conclusions of the investigation.

The report also includes the following Appendices:

- Appendix A: Selected Figures Form Previous Reports
- Appendix B: Inyo County Well Permits
- Appendix C: Test Borehole Logs and Well Construction Logs
- Appendix D: Geophysical Logs
- Appendix E: Sieve Analysis Results
- Appendix F: Groundwater Elevation Information and Groundwater Potentiometric Contour Maps
- Appendix G: Groundwater Level Transducer Data
- Appendix H: Groundwater Level Hydrographs
- Appendix I: Spring Flow Hydrographs
- Appendix J: Aquifer Test Analysis Methodology and AQTESOLV Solutions
- Appendix K: Groundwater Laboratory Results
- Appendix L: Groundwater Modeling Methodology

2.0 GENERAL SITE INFORMATION AND WELL INFORMATION

2.1 General Site Information

The site, locally known as the Cabin Bar Ranch, is an irregularly-shaped property that consists of approximately 420 acres. The site is in Section 1, Township 19 South, Range 36 East and Sections 5 and 6 Township 19 South Range 37 East as shown on the United States Geological Survey (USGS) 7.5 minute Olancha Topographic Quadrangle (**Figure 1**). Adjacent to site on the north is the community of Cartago. The town of Olancha is located approximately 3 miles to the south.

Regionally, the site is located in the southern portion of the Owens Valley. Owens Lake (dry lake bed) is located east of the site, and the base of the Sierra Nevada Mountains is located 1 mile west of the site. Highway 395, which runs north-south, crosses the western portion of the site (**Figures 1 and 2**). The Los Angeles Aqueduct is located approximately ½ west of the site and Cartago Creek, which is a ephemeral stream, runs east-west across the site.

CGR recently purchased the ranch site from Anheuser Busch Company in 2010. Prior to the purchase the site was used for cattle ranching and currently has numerous existing ranching facilities, including ranch houses, corals, irrigation ditches, and a reservoir (**Figure 2**). The main ranch house is located on the northern portion of the property. The current caretaker's house, along with several old houses and barns, is located in the southern portion of the site. Livestock was generally grazed in the meadow areas located in the eastern portion of the site. The meadow area was flood irrigated by a system of irrigation ditches, including a main collection ditch that is approximately 2,000 feet long and approximately 3 to 6 feet deep (James M. Montgomery [JMM], 1993). Currently, the main collection ditch is kept full of water from groundwater seepage and natural spring flow on the west side of the ditch. Flow from the main collection ditch into the system of smaller ditches located in the meadow area was controlled in the past by a series of gates (JMM, 1993). A large irrigation reservoir was also used for water supply on the ranch (**Figure 2**).

The old cattle ranch had four wells that were used for water supply. These wells are labeled CBR-1, CBR-2, CBR-3, and CBR-4 and were described by JMM (1993). The locations of the wells are shown on **Figure 2**. CGR-1 is reported to be 198 feet deep and currently used to supply the main ranch house. CGR-2 is an artesian well located on the north bank of Cartago Creek and is reported to be approximately 186 feet deep. CBR-3 is a shallow 10-foot well that was installed at a former spring. It was used to water live stock. CBR-4 is a 60-foot well and presently used for water supply at the caretaker's

residence. A deep production well (PW-1) is also located on the western portion of the site (**Figure 2**). This well was installed by Anheuseur Busch for a proposed water export project (JMM, 1989 and 1993). Available completion depth and screen interval information for the domestic wells and the production well is presented in **Table 1**. A summary of monitoring wells and piezometers installed by Anheuser-Busch, as part of an environmental impact study is presented in Section 4.0.

2.2 Active Off-Site Production Wells

CGR currently operates a bottled spring water facility on the property located immediately south of the site. CGR reports that four wells are currently used for water sources. Two wells, CGR-2 and CGR-7 are used for spring water production and two wells, CGR-3 and CGR-4, are used for bottle rinsing and domestic purposes (**Figure 3**). There are also numerous other wells, including old domestic wells and monitoring wells on the CGR southern property. CGR reports that recent annual groundwater pumping at their Olancha bottling facility is between approximately 275 and 325 acre feet per year (AFY) (CGR, personal communication, 2010).

The Cartago Mutual Water Company (CMW) owns two wells, CMW-1 and CMW-2, located north of the northern site boundary (**Figure 3**). The CMW distributes water to residences of the town of Cartago. JMM (1993) also reported about 20 active domestic wells in Cartago at the time of the Anheuser-Busch environmental impact study in the early 1990s. Recent groundwater pumping information for the Cartago area was not obtained as part of this investigation.

3.0 REGIONAL GEOLOGY AND HYDROGEOLOGY

The site is located in the southern portion of the Owens Valley which has a length of 150 miles and width of generally less than 8 miles. The Owens Valley is the westernmost valley of the Basin Range Province and is formed by the Sierra Nevada Mountains to the west and the White/Inyo Mountains to the east. The Sierra Nevada Mountains are generally composed of Cenozoic age igneous rocks of granodiorite-granite composition whereas the White/Inyo Mountains, to the east, consist of Pre-Cambrian to Triassic sedimentary rock locally intruded with Cenozoic granitic rocks.

Structurally, the Owens Valley is a graben bounded by the Sierra Nevada Frontal Fault and the Inyo Mountain Frontal fault. These faults are considered active and the offset on these faults is the cause of the dramatic relief in the Owens Valley area. The site is located on the valley floor at an elevation of approximately 3,640 feet, while Olancha peak, to the west of the site in the Sierra Nevada Mountains, stands at an elevation of over 12,000 feet. The Inyo Mountains east of the site have an elevation greater than 8,000 feet.

The California Department of Water Resources (2003) shows the site to be located in the southern portion of the Owens Valley Groundwater Basin. The groundwater basin has a surface area of 1,030 square miles and includes valleys in both Mono and Inyo County. The basin, as defined by the Department of Water Resources, is bounded to the south by the Coso Range, the Sierra Nevada to the west, the White/Inyo Mountains to the east, and the Benon Range to the north. Groundwater occurs in the sediments that fill the valley. The most important water bearing formation in the vicinity of the site is alluvium consisting of sands and gravels that is derived from erosion of the surrounding mountains. The sandy and gravelly alluvium is locally interbedded or interfingered with fine-grained lacustrine (lake) deposits. The thickness of the alluvial and lacustrine sequence is thought to be several thousand feet thick and up to 6,000 feet or more in the middle of the Owens Lake (Pakiser et. al., 1964).

The primary source of groundwater recharge in the Owens Valley Groundwater basin is from percolation of stream flow from the surrounding mountains. In the case of the site and the Cartago area, the main aquifer is thought to recharge primarily by flow in Cartago Creek and Braley Creek that have watersheds to the west of the site in the Sierra Nevada Mountains. Stream flow in these creeks is derived from precipitation in the mountains and infiltrates through relatively permeable alluvium closer to the valley floor. There is also thought to be some recharge of the alluvium from underflow of groundwater in fractures in the mountain bedrock, although the volume of such recharge is not known. Recharge of direct precipitation into the alluvium may also contribute a relatively small component of recharge into the groundwater basin.

4.0 PREVIOUS HYDROGEOLOGIC SITE STUDIES

Numerous hydrogeologic site studies have been performed in the past. The major findings of these studies are presented below.

In the late 1970s and early 1980s several hydrogeologic investigations were conducted (Leroy Crandall, 1978; Geothermal Surveys Inc. [GSI], 1982, and GSI, 1983).[1] These investigations first identified a fault in the alluvium that underlies the site. GSI (1982) reported that the fault ran parallel to the main irrigation ditch and suggested that the springs on the ranch were fault controlled. This fault has more recently been called the "Spring-Line fault". A series of springs and seeps were identified along the fault scarp that included 5 major springs that flowed between 60 and 120 gallons per minute (gpm). Two of the large springs reported to be on the ranch site by GSI appear to be located on the property south of the site. Total spring and seep flow was estimated at approximately 800 gpm (Leroy Crandall, 1978 and GSI, 1983). The investigators indicated that the springs flowed into the main collection ditch. The investigator hypothesized that the marshlands or meadows in the eastern part of the site represented a rise of groundwater to the surface where it encounters increasing finer lake sediments and surface discharge from springs that rise on the Spring-line fault (GSI, 1983).

GSI (1982) estimated an available groundwater supply beneath the site by estimating the groundwater recharge in the Cartago Creek Watershed to the west of the site. Using recharge information collected by Lee (1912), GIS preliminarily estimated that approximately 2,400 acre feet per year (AFY) of groundwater supply was available to the ranch without depleting the groundwater basin.

Anheuser-Busch Company purchased the Cabin Bar Ranch in the mid 1980s and contracted JMM to conduct a series of hydrogeologic investigations and a comprehensive Environmental Impact Report. During their investigations JMM installed a deep 16-inch diameter water production (PW-1) well located west of Highway 395 (**Figure 2**). PW-1 was completed at depth of 660 feet below ground surface (bgs) in the alluvial aquifer (JMM, 1989). JMM also installed four deep monitoring wells (MW-1 through MW-4) and sixteen shallow piezometers (P-1 and P-16). The monitoring wells were completed at depths ranging between 84 and 615 feet bgs. The shallow piezometers were screened in the upper portion of the aquifer beneath the site or the "shallow production zone". The purpose of the piezometers was to monitor shallow groundwater conditions beneath the site. JMM (1987) reported that the springs on the site were relatively large in areal extent

[1] The Leroy Crandall, 1978 report was not available to Geosyntec for review, but was cited several times by Geothermal Surveys, 1982 and 1983.

and non-distinct in nature, consequently JMM chose to monitor spring flow indirectly by locating piezometers near the springs. The general conclusions regarding spring characteristics made by JMM is somewhat in contrast to observations made by GSI (1982) who noted five distinct large springs in addition to numerous small springs and seeps. **Table 1** presents the available completion depth and screen interval information for the JMM wells and piezometers. The locations of the piezometers and wells are shown on **Figure 2**. It should be noted that MW-4 was reported to be destroyed by JMM and piezometers P-14 and P-16 could not be located in the field by Geosyntec in 2010.

JMM (1993) described the geology of the site, based largely on drilling data. Their interpretive cross-section is presented in **Appendix A, Figure A-1**. JMM indicated that the site overlies a transition zone between alluvial deposits derived from erosion of the Sierra Nevada Mountains to the west and the lacustrine deposits to the east. The alluvial deposits in the western portion of the site consist of boulders, gravels and sands with relatively little fine-grained sediment. Farther east, the alluvial deposits intermingle with the fine-grained lacustrine deposits and the overall nature of the sediments beneath the site fine to the east. For example, JMM (1993) noted that boulders were encountered in PW-1, but not in MW-1 (**Figure 2**). Based on drilling data and surface morphology, JMM (1993) inferred that the ancient Owens Lake lakeshore was formerly located in the vicinity of the site thousands of years ago. Alluvial materials derived from the Sierra Nevada Mountains were deposited along the lakeshore while fine-grained lacustrine materials were deposited in the shallow lake waters. As the elevation of the lake varied, the shoreline moved laterally, causing interfingering of the coarse alluvial materials and the fine-grained lake deposits. Geosyntec generally agrees with this interpretation (see Section 7.0). A block diagram presented in JMM (1993) is presented in **Appendix A, Figure A-2** that depicts this interpretation of the general site geology.

JMM contracted Dr. Kerry Sieh (1989) to perform a fault study on the site. Dr. Sieh noted evidence of a linear topographic scarp parallel to the main collector ditch with a surface displacement of 1 to 3 feet, and verified the location of the GSI (1982) Spring-line fault.

JMM (1989 and 1993) conducted an aquifer test in PW-1 in May 1989. PW-1 was pumped at 2,800 gallons per minute (gpm) for 14 days. The salient results of the aquifer test are as follows:

(1) Transmissivity of the deeper alluvial production zone, located at a depth of approximately 150 to 600 feet beneath the site, was estimated at 26,000 feet squared per day (ft^2/day) and the hydraulic conductivity was estimated at 40-60 feet/day (ft/day). These values are consistent with a very coarse-grained aquifer.

(2) No significant hydraulic boundaries of low permeability, such as a vertical fault or bedrock surface, were indicated by the test. However, the Spring-line fault located near the main collection ditch appears to cause a small rise in groundwater levels and thus would represent at least a semi-permeable boundary.

(3) The hydraulic conductivity of sediments underlying the site is vertically anisotropic. That is, horizontal hydraulic conductivity was noted to be higher than vertical hydraulic conductivity. Vertical leakage from zones above the deeper production zone during the test was also interpreted. The findings support the model of interfingering coarse-grained alluvial materials with fine-grained lacustrine deposits described above.

JMM (1993) presented a thorough discussion of annual groundwater recharge in the watershed area of the site. The site watershed area was estimated at approximately 16,500 acres and included the Cartago Creek, Braley Creek and adjacent unnamed watersheds between Cartago and Olancha Creek (Braley Creek is located north of Cartago Creek and Olancha Creek is located south of Cartago Creek). The watershed area is shown in **Appendix A, Figure A-3**. JMM estimated that the total average annual groundwater recharge to the CBR-Cartago area is at least 2,400 AFY (which is equal to the GSI 1982 estimate) and may be as high as approximately 4,000 AFY.

5.0 DRILLING AND INVESTIGATION METHODOLOGY

The following sub-sections present the investigative methodology of site reconnaissance, drilling, well installation, piezometer installation, aquifer testing, and groundwater and spring water sampling performed at the Cabin Bar Ranch property between December 2009 and November 2010. The results of these investigations are presented in Section 6.0.

5.1 Site Reconnaissance and Flume Installation

In December 2009, Geosyntec performed a preliminary site reconnaissance to locate springs and observe general site conditions. Geosyntec observed numerous springs and seeps along an apparent fault scarp located parallel to the main collection ditch. Nine spring locations (CBS-1 through CBS-9) were marked for surveying (**Figure 2**), including the two with the largest observed spring flow (CBS-6 and CBS-9).

In order to evaluate the flow rates from selected springs, Geosyntec selected Baski, Inc. 18–inch long, cutthroat flumes to be temporarily installed at springs CBS-2, CBS-4, CBS-6, and CBS-9. The cutthroat flumes were installed on March 29 and 30, 2010 near the head of each spring to capture water flowing from the spring. Sand bags were placed on the outside of the flumes to hold them in place and level. The flow through the flumes was set so that the water height on the downstream height of the flume was at least half the height on the upstream side in accordance with manufacturer's specifications.

5.2 Drilling and Well Installation

5.2.1 Testhole Drilling, Geophysical Log, and Sieve Analyses

Four test holes (TH-1 through TH-4) were completed to evaluate site lithology and geophysical properties. The test holes were completed between May 24, 2010 and May 27, 2010. The approximate testhole locations are shown on **Figure 2**. Test holes were located approximately 250 feet from corresponding spring locations. Test holes borings were completed using a VersaDrill mud-rotary drill rig operated by Gregg Drilling and Testing, Inc. (Gregg Drilling) from Signal Hill, California. The mud rotary rig was equipped with a four-inch diameter drill bit. Lithologic samples were collected at five and ten foot intervals during drilling starting at 10 feet below ground surface (bgs). Samples were obtained using a California split-spoon sampler equipped with 2.5-inch diameter, 6-inch long brass sample sleeves. The lithologic samples were logged under the Unified Soil Classification System (USCS) by licensed California Professional Geologists. Logs of the test holes are presented in **Appendix C**.

Welenco Inc., of Bakersfield California, was contracted to conduct down-hole geophysical surveys in the test holes after drilling was completed. Spontaneous potential and electrical resistivity logs were run in the boreholes. Geophysical logs are presented in **Appendix D**. Following testhole completion, the boreholes were backfilled and sealed at the surface using a hydrated bentonite and cement slurry.

A selection of three representative soil samples from each of the test holes collected at target well screen depths, were sent to Roscoe-Moss Inc. in Los Angeles, California for grain-size analysis (**Appendix E**). The sieve grain-size analysis was used to design gravel pack and well screen slot size.

5.2.2 Test Well Installation

Three test wells (CGR-8, CGR-9 and CGR-10) were installed at the site based on data obtained during the testhole investigation including borehole logs, geophysical logs, and sieve analysis results. Prior to installation Inyo County Environmental Health Services Well Permits were obtained (**Appendix B**). The test wells were installed approximately 250 feet from an identified spring area and installed within the same shallow aquifer that the spring derives it groundwater from. The test wells were designed to meet both State of California community well construction standards and to meet the state and federal definitions of a bottle water spring source. The locations of the test wells are shown on **Figure 2**.

The wells were drilled and installed by Gregg Drilling, using a mud-rotary drill rig equipped with an 18-inch diameter bit. Woy-Ben Gel mud was circulated during drilling in order to maintain borehole stability and facilitate recovery of drill cuttings. During drilling, soil samples were obtained from the cuttings of the drill rig which were separated from the drilling mud using a shaker. Samples were generally collected every 5 feet bgs. A Geosyntec licensed Professional Geologist monitored drilling operations and maintained a log of drill cuttings and recorded pertinent observations during the drilling of well boreholes.

CGR-8, CGR-9, and CGR-10 were constructed using 10-inch diameter 316-gauge stainless steel blank casing and continuous wrap 0.070-inch slotted stainless steel screen. The top of the casing for the wells was installed at approximately 2.5 – 3 feet above ground surface. The filter pack and well screen slot size were designed in general accordance with methods outlined in Driscoll (1989) using the results of the sieve analysis. The blank well casing and wire-wrap screen materials were constructed by Roscoe Moss, Inc. of Los Angeles, California. **Table 2** presents a summary of the well construction details for the CGR-8, CGR-9 and CGR-10. Well Driller Reports are presented in **Appendix B** and well construction details are also presented in **Appendix C**.

The filter pack used for the well installation was #4x#12 CEMEX Coarse Aquarium sand. A sanitary seal was installed in the annulus of each well from 50 ft bgs to ground surface. The sanitary seal consisted of a 3 foot layer of medium Enviroplug bentonite pellets from approximately 47 to 50 feet bgs and a neat cement seal from 47 ft bgs to ground surface. The neat cement mixture was produced by adding approximately 5.2 gallons of water to each 94 pound bag of Portland cement. The pellets were installed by pouring them into a tremie pipe placed at the bottom of the filter pack. Each well annulus was consistently sounded with a weighted drillers tape to insure that no bridging had occurred. The pellets were allowed to hydrate for approximately 15 to 30 minutes before neat cement was mixed and pumped into the annulus above the hydrated bentonite. A representative from Inyo County Environmental Health Services was on site to witness the placement of the annular seal for all three wells. Following installation of the wells, a 4- by 4-foot concrete pad was installed at ground surface around the well risers.

5.2.3 Well Development

Following installation, each well was developed. The newly installed wells were allowed to stand for a minimum of 72 hours before development operations were started. Well development operations were performed in August 2010. Each well was brushed and bailed; air lifted using an air lift tool and air compressor, and then surged and pumped. A step-test was then performed to preliminarily estimate well specific capacity.

Initially, the blank and screened portions of each well were brushed using spirally-wound nylon bristles that were mounted on 4-inch maximum diameter by 20-ft length weighted core. The brush fit snugly within the casing and screen so that an effective swabbing action was achieved with movement of the brush and provided stresses within the filter-packed annulus and the near-well zone in an attempt to move the fine-grained material. Brushing was conducted for approximately one minute per wetted foot of blank casing and two minutes per foot of well screen.

Following brushing, a swab/airlift tool with a double rubber packer assembly (i.e., double surge block) was placed in each well at the top of the screened interval and preceded downward. Swabbing was completed to mechanically dislodge fine-grained sediment and residual drilling fluid from the filter pack and near-well zone of the aquifer. Simultaneously with the swabbing action, the loosened materials were removed by airlifting. An Imhoff cone was used to monitor development progress by measuring the quantity of sand and silt being removed. The amount of silt and sand per screen interval was recorded approximately every 15 minutes of air lift development.

Following air lifting, each well was surged and pumped with an electric submersible pump until the turbidity of the groundwater removed from the wells was reduced below

5 NTUs and the sand content was less than 2 milligrams per liter (mg/L). Specific capacity testing of each well was performed to assess likely well response (drawdown) to pumping. The flow rates were monitored during pumping using a totalizer gauge that was certified in July 2010. A "Rossum" centrifugal sand tester was installed in the discharge line to measure the sand content during final development. During specific capacity testing, flow rates were varied and ranged from 100 to 400 gpm. Water quality readings of pH, temperature, turbidity and electrical conductivity were monitored using a Horiba U-10 hand held instrument during development to evaluate whether water pumped from the well was representative of formation groundwater and flowing from the aquifer.

5.3 Piezometer Installation

Four temporary shallow piezometers (RP-1 through RP-4) were installed in locations approximately 5-8 feet from the head of springs CBS-2, CBS-4, CBS-6, and CBS-9 (**Figure 2**). The piezometers were installed on September 8-9, 2010. A three-inch diameter hand auger pilot boring was completed near the head of each spring, to a depth of approximately 5 ft bgs, at which point the borehole would not stay open due to flowing sand conditions. Once the sands were encountered the screen section of the piezometer was then driven into the sand using a sledge hammer.

Field lithologic observations and construction details for RP-1 through RP-4 are provided in **Table 3**. Each piezometer was constructed using a two-foot long, one-inch diameter, 0.020-inch screen section made of stainless steel with a drive point threaded onto an approximate seven-foot long section of galvanized Schedule 40 pipe. The piezometers were hand driven using a sledge hammer to depths ranging from 6 to 8 feet bgs. A sand pack of #4x12 coarse aquarium sand was poured into the portion of the borehole containing groundwater that remained open, and the remainder of the open borehole above the groundwater table was sealed using hydrated bentonite pellets. A riser of blank galvanized casing of approximately 2-3 feet in height was completed above ground.

Each piezometer was hand surged and bailed using a 5/8-inch bailer to remove fine-grained material from the screen section and to promote flow of groundwater into the piezometers. The piezometers were bailed until the groundwater produced was relatively free of suspended sediment.

In addition to the shallow piezometers a standpipe (RP-5) was installed in the main irrigation ditch on September 9, 2010 to monitor surface water levels. The location of the standpipe is shown on **Figure 2**. The standpipe was constructed with the same materials as the piezometers described above. The position of the standpipe was secured in the ditch with cinder blocks at the ditch bottom to hold it vertically in place.

5.4 Aquifer Testing

Aquifer testing was conducted in test wells CGR-8, CGR-9, and CGR-10 to estimate hydrogeologic properties (transmissivity and hydraulic conductivity) of the shallow aquifer beneath the Site. The following section describes the procedures and methodology of the aquifer testing performed at the site between September and November 2010.

A 72-hour constant rate aquifer test was conducted at each well (CGR-8, CGR-9, CGR-10). Each aquifer test was followed by a 24-hour recovery monitoring period. Prior to starting each test, an initial or pre-pumping groundwater level reading was collected from the associated piezometers and wells, and at the springs using a hand held electric water level indicator. The initial water level readings were recorded. Additionally, 13 data loggers (pressure transducers) were installed; one in each of the newly installed test wells and selected piezometers. A 10-horsepower Mitsubishi electric submersible pump connected to a 75-kilowatt generator was used for pumping in the test wells. The intake of the pump was placed at approximately 50 feet bgs in each test well, directly above the top of the screened interval of each well.

A pump rate of approximately 170 gpm was maintained throughout the duration of each 72-hour test. The pump rate of 170 gpm was selected based on CGR's maximum production flow rate of approximately 500 gpm, or approximately 167 gpm per well (CGR-8, CGR-9 and CGR-10).[2] The flow rate was monitored periodically using an in-line totalizing flow gauge that accurately measured the flow in gpm and the total gallons pumped during the test. Flow rates were adjusted using a gate valve. Once pumping was initiated, manual flow and water level measurements were collected periodically at the spring flumes and selected piezometers.

During each test, manual water level measurements (depth to water) were taken initially in the pumping well to evaluate pumping well groundwater drawdown. Additionally, the springs (CBS-2, CBS-4, CBS-6 and CBS-9) and southern facility springs (ES-1 and ES-3A) were monitored a minimum of approximately once every hour during the first day of pumping to evaluate spring-flow reduction. Groundwater level measurements in all wells and piezometers were collected once per day, and spring readings were conducted

[2] The 500 gpm rate of pumping is based on a maximum build out of four bottling lines running at 125 gpm each. CGR is proposing an average annual water use of 360 AFY at the Cabin Bar Ranch. The 360 AFY figure equates to an average pumping rate of approximately 223 gpm. The proposed water use estimate (360 AFY) for the Cabin Bar Ranch is from a Project Description submitted to the Inyo County Planning Department.

three times per day for the remainder of the test. Monitoring of the springs, wells, and piezometers across the site was conducted just prior to stopping the pumping.

Following 72 hours of pumping, a 24-hour recovery monitoring period was completed. The recovery monitoring was completed for both the spring locations, and well and piezometer locations. The recovery monitoring continued at the selected monitoring locations until a minimum of 95% of the initial water level or flow recovered or until 24 hours after pumping in the test well ended.

During pumping, the discharge water was conveyed via above-ground pipes to an area east of the spring line located approximately 500 feet northeast of piezometer P-15. The water was discharged to the land surface (**Figure 2**). The land surface discharge area to the east of the site is generally open fields where the pumped water can eventually infiltrate back into the subsurface. The discharge water did not leave the property, or enter any existing bodies of surface water.

Specific details of each test are outlined below.

5.4.1 Well CGR-8 Aquifer Test

The 72-hour constant-rate aquifer test was conducted on well CGR-8 starting on October 15, 2010, at approximately 9:00 am. Transducers were placed in wells CGR-8, CGR-9, CGR-10, and OW-7U, and in piezometers RP-1 through RP-4, P-1, P-4, P-10, P-15, and in the irrigation ditch at location RP-5 (**Figure 2**). The transducers were synchronized and set to start at 9:00 am and the pumping was started a few seconds after the scheduled start time. The pump was stopped after 72 hours of pumping at 9:00 am on October 18, 2010 and recovery monitoring was conducted for the next 24 hours.

5.4.2 Well CGR-9 Aquifer Test

The 72-hour constant-rate aquifer test was conducted on well CGR-9 starting on September 17, 2010, at approximately 8:00 am. Transducers were placed in wells CGR-8, CGR-9, CGR-10, and OW-7U, and in piezometers RP-1 through RP-4, P-2, P-10, P-12, P-15, and in the irrigation ditch at location RP-5. The transducers were synchronized and set to start at 8:00 am. The pump was stopped after approximately 72 hours of pumping at 9:30 am on September 20, 2010 and recovery monitoring was conducted for the next 24 hours.

5.4.3 Well CGR-10 Aquifer Test

The 72-hour constant-rate aquifer test was conducted on well CGR-10 starting on November 12, 2010, at approximately 9:00 am. Transducers were placed in wells CGR-8,

CGR-9, CGR-10, and OW-7U, and in piezometers RP-1 through RP-4, P-5, P-10, P-11, P-15, and in the irrigation ditch at location RP-5. The transducers were synchronized and set to start at 9:00 am. The pump was stopped after 72 hours of pumping at 9:00 am on November 15, 2010 and recovery monitoring was conducted for the next 24 hours.

5.5 Groundwater Sampling

Groundwater samples were collected from the pumping well for certification and compliance purposes by CGR at the end of each aquifer pump test. The samples were collected from an in-line sample port near the well head assembly, using bottles supplied by the analytical laboratory. After collection the samples were immediately placed in an ice chest and cooled with ice. The water samples were collected in appropriate laboratory bottles supplied by Compliance Designs, Inc of Weare, New Hampshire. The samples were shipped to the analytical laboratory under chain-of-custody. The samples collected were analyzed for a variety of analytical suites including general minerals, general physical characteristics, inorganic metals, organic chemicals (herbicides and pesticides), volatile organic compounds (VOCs), semi-volatile organic compounds (SVOCs), radiological compounds, microbiological quality, dioxin and perchlorate. The laboratory methods are presented in **Appendix K**.

6.0 INVESTIGATION RESULTS

The following sections present results of the hydrogeologic investigation conducted at the site between December 2009 and November 2010.

6.1 Summary of Site Reconnaissance

Field reconnaissance of the site generally supported previous observations made by JMM 1993 (see Section 4.0). Numerous small to moderate flowing springs are present on the site. The springs are located in the southern portion of the site and occur along a lineament that parallels a man made water collection ditch (i.e., main collection ditch). Groundwater emanating at the surface in the spring locations generally occurs along a 1- to 5-foot rise in ground surface elevation that has been interpreted as a fault scarp (see Sections 4.0 and 6.3). The fault scarp is located adjacent and to the west of the main collection ditch. **Figure 4** shows the trace of the fault scarp as interpreted by Geosyntec field geologists. The fault has a northwest trend and is observable on the property from approximately Cartago Creek to the south of the site. Moderate spring flow on the southern property (ES-1 and ES-3A) also occurs along the fault line. This fault has been referred to as the Spring-line fault in previous site investigations (GSI, 1983 and JMM, 1993),

During Geosyntec's field reconnaissance in December 2009, nine obvious spring locations were identified (CBS-1 through CBS-9). The locations of these nine springs are shown on **Figure 2**.[3] Most of the springs observed on the site appeared to have flow rates of approximately 1-2 gpm. Two larger springs CBS-6 and CBS-9 have flow rates of approximately 8-10 gpm. These flows were estimated visually and confirmed in 4 of the springs through installation of four temporary cut-throat flumes in March 2010 at locations CBS-2, CBS-4, CBS-6, and CBS-9.

Spring flow was observed to generally flow eastward into the main collection ditch (**Figure** 2). Water in the collection ditch then generally runs northward or southward along the ditch and then flows eastward into the eastern meadow where low areas occur. Eastward flow out of the main collection ditch and into the meadow was observed at two locations. One location is a low channel area and the other an installed pipe. Total flow at these two locations was estimated at approximately 350 gpm. Because of grass cover in the meadow area there may be other locations where eastward flow out of the ditch occurs but was not observed by Geosyntec. The observed flow out of the main ditch is significantly greater than observed spring flow that enters the ditch from the west. The

[3] Other springs are likely to occur on the site that are seasonal or that are covered by vegetation.

difference is interpreted to be the result of groundwater discharging directly into the ditch from the bottom and sidewalls of the ditch (i.e., groundwater seeping into the ditch). It should also be noted that spring water at CBS-9, which is not located adjacent to the collection ditch, appears to flow eastward and then rapidly percolates into the subsurface.

6.2 Summary of Drilling Results and Well Installation

Lithologic logs for the test holes and wells, including well construction details are presented in **Appendix C**. **Figure 2** shows approximate locations of four test holes (TH-1 through TH-4) completed at the site and the locations of test wells CGR-8, CGR-9, and CGR-10. The drilling information is summarized in site cross-sections presented in **Figures 5 and 6** which are discussed in more detail in Section 6.3.

During drilling unconsolidated sedimentary deposits consisting primarily of alluvium and lacustrine deposits were encountered. A highly organic, black clay or peat material with abundant plant material was encountered near the surface to approximately 10 feet bgs in several site borings. Between approximately 10 feet bgs and approximately 80 feet bgs unconsolidated, interbedded light brown to brown, fine to very coarse-grained, poorly and well graded sands were observed. Additionally, thin poorly graded gravel layers less than 2-3 feet in thickness were generally identified from between 55 and approximately 75 to 80 feet bgs. The gravels are composed of a light brown to reddish brown, sub-rounded, granitic clasts. Starting at about 75 to 80 feet bgs fine-grained material consisting of dark gray to black, organic silt with clay, and very fine poorly graded sand was encountered. The fine-grained materials contained small shell fossils and a slight sulfide odor. When the fine grained material was encountered during drilling, a distinct color change in the drilling mud was observed. These fine-grained materials were generally encountered to a depth of 90 feet bgs. The fine-grained material are underlain by interbedded, fine to coarse, poorly graded to well graded sands with gravel from approximately 90 feet bgs to the total depth explored of 100 feet bgs. Gravels encountered below the fine-grained units were composed of light gray to dark gray sub-angular granodioritic clasts, and when encountered a change in the color of the drilling mud was observed.

Geophysical logs for the test boreholes are presented in **Appendix D**. The logs confirm field geologist's observations during drilling. Both the resistivity and gamma logs are similar for the four test holes indicating general continuity of stratigraphy across the site. The resistivity logs show a sharp decrease in resistivity starting at approximately 75-80 feet bgs. The significant decrease is resistivity is interpreted to indicate the top of the fine-grained silt and clay layer observed in the boreholes. A sharp increase in gamma activity was also generally recorded starting between approximately 70-80 feet.

The increase in gamma activity is interpreted to be the result of the increase abundance of gamma producing elements generally more abundant in fine-grained clay type materials.

The sandy and gravelly materials encountered from 10 to approximately 80 feet bgs during drilling are interpreted to be alluvium. The fine-grained materials encountered at approximately 75 to 80 down to a depth of approximately 90 feet bgs are interpreted to be lacustrine deposits. The lithology encountered at the site during drilling is very similar to lithology encountered south of the site at CGR's southern facility (wells CGR-2, CGR-4, etc). The sandy and gravelly alluvium above 80 feet is interpreted to be part of the shallow production zone proposed by JMM (1993) and in this report is called the Shallow Zone.

Selected lithologic samples were sent to Roscoe-Moss, Inc for grain size distribution analysis (**Appendix E**). The results indicated that generally the dominant grain size distribution by weight was within the very coarse- to medium-grained sand size range.

6.3 Site Geologic Cross-Sections

Two site geologic cross sections were prepared using data from borings completed during this investigation and from previous investigations (Dames & Moore, 1992 and 1995 and JMM, 1993)). **Figure 4** presents the lines of cross-section, and **Figures 5 and 6** present cross sections A-A' and B-B', respectively. Cross-section A-A' is a west to east cross-section and includes deeper boring information presented in JMM (1993). Cross-section A-A' shows thick packages of coarse alluvium layers in the very western portion of the site that are shed off of the Sierra Nevada Mountain range and transported down slope towards the valley floor. In the eastern portion of the site the fine-grained silt-clayey layers, interpreted to be lacustrine deposits deposited in ancient Owens Lake, are shown to be interbedded with the sandy alluvium. The Spring-line fault is shown in cross-section A-A'.

Cross-section B-B' is a north to south cross-section and generally includes drilling information for the upper 100 feet. Cross-section B-B' shows the stratigraphy in the Shallow Zone across the southern portion of the site where wells CGR-8, CGR-9 and CGR-10 were completed. The organic rich fine-grained layer (silt, clay and very fine sand) that was encountered at approximately 80 feet bgs is shown to be laterally continuous and extends south of the site. The top of fine-grained layer occurs at an elevation of approximately 3,540 and 3,550 feet MSL and is interpreted to be a lacustrine deposit. The three site test wells and the water production wells to the south, including CGR-2 and CGR-4, are all completed above this fine-grained layer (see following section).

6.4 Test Well Installation

Based on information collected in the test boreholes, three test wells were completed: CGR-8, CGR-9 and CGR-10. Well construction details are summarized in Section 5.2.2 and **Table 2**. The wells were completed in the shallow portion of the alluvial aquifer beneath the site (Shallow Zone). Cross-sections (**Figures 5 and 6**) show the screen intervals of the wells. The wells were constructed in accordance with State of California Community Well Standards. The wells were also designed to be approved as bottled spring water sources in accordance with state and federal standards. According to state and federal bottle spring water standards, both the well and spring system must derive their water from the same underground stratum, and the well and spring system must be in direct hydraulic communication.

6.5 Groundwater Levels and Potentiometric Surface Contour Maps

Groundwater elevation levels and groundwater potentiometric surface contour maps for the Shallow Zone are presented in **Figure 7** and **Appendix F**. Groundwater elevations were collected as part of the aquifer testing program described below.

Groundwater levels were collected prior to the start of each test on September 21, 2010, October 15, 2010 and November 12, 2010. The potentiometric surface contour map for October 15, 2010 is presented as **Figure 7** while the contour maps for all three events (pre-test) are presented together in **Appendix F** (**Figures F-1, F-4 and F-7)**. Groundwater elevations and the potentiometric surface maps generally show the same pattern on these three pre-pump test dates. Groundwater elevations ranged from approximately 3,605 feet above MSL in the eastern most piezometer (P-15) to approximately 3,618 to 3,619 feet above MSL in the western most piezometers (P-1, P-5, P-7, P-8 and P-10). Groundwater levels occur near the ground surface in the eastern most piezometers and at depths near 20 feet bgs in the western piezometers.

Groundwater potentiometric surface contour maps (**Figure 7 and Figures F-1, F-4, and F-**7) indicate that the shallow groundwater flow direction is eastward. That is, shallow groundwater beneath the site is flowing away from the Sierra Nevada Mountains and the top portions of the bordering alluvial fans where a large amount of groundwater recharge is occurring and towards the Owens Valley dry lake bed. The average gradient across the central portion of the site is approximately 0.015.

6.6 Aquifer Testing Results

The following sections present results of aquifer tests conducted at the site between September and November 2010. Transducer data collected for each of the three aquifer pump tests are included in **Appendix G**. Hydrographs of groundwater levels recorded by pressure transducers during each of the aquifer tests are included as **Appendix H**. Hydrographs of spring flow recorded from the spring flumes during each of the aquifer tests are included as **Appendix I**. The aquifer test software program AQTESOLV Version 4.0 was used to analyze drawdown data in selected observation wells to estimate the transmissivity and hydraulic conductivity of the shallow zone. Aquifer test methodology and solutions for the three tests are included as **Appendix J**.

6.6.1 Well CGR-8 Aquifer Test

The 72-hour constant-rate aquifer test was conducted on well CGR-8 starting on October 15, 2010, at approximately 9:00 am and ending at 9:00 am on October 18, 2010. The well was pumped at average rate of approximately 170 gpm. See Section 5.4 for more specific details on aquifer test methodology.

6.6.1.1 Groundwater Level Measurements

Tables F-1 through F-3 in **Appendix F** present groundwater level measurements collected prior to pumping, after approximately 72 hours of pumping (end of test), and after 24 hours of recovery. **Figures F-1 through F-3** in **Appendix F** present shallow groundwater potentiometric surface contour maps for these three monitoring events.

The groundwater elevation hydrographs for wells and piezometers with transducers for the CGR-8 pump test (**Appendix H1**) include a week of background data collected prior to the test and after the test.[4] Relatively minor drawdown of groundwater levels was observed in most of the wells and piezometers monitored. The drawdown in the pumping well CGR-8 after 72 hours of pumping was measured at 8.89 feet. The specific capacity of CGR-8, defined as pumping rate divided by drawdown after 72 hours of pumping, was calculated to be 19.1 gallons per minute per foot of drawdown (gpm/ft).

[4] Transducers in piezometer P-1 and P-4 were moved in preparation for the CGR-10 pump test and therefore a full week of data following the CGR-8 pump test was not recorded.

The table below is a summary of water levels in key wells or piezometers measured prior to pumping and after approximately 72 hours of pumping.

Changes in Groundwater Elevations in Selected Monitoring Locations - CGR-8 Aquifer Test

Well / Piezometer ID	Approx. Distance to Pumping Well (ft)	Groundwater Elevation Before Pump Test (ft msl)	Groundwater Elevation at End of 72-Hour Pump Test (ft msl)	Change in Water Elevation (ft)
CGR-8	0	3616.59	3607.70	-8.89
CGR-9	700	3617.61	3617.12	-0.49
CGR-10	1,230	3618.38	3618.08	-0.30
P-10	3,040	3619.93	3619.87	-0.06
OW-7U	330	3616.27	3615.72	-0.55
P-4	120	3616.68	3615.87	-0.81
P-13	260	3615.83	3615.20	-0.63
P-15	830	3605.21	3605.32	0.11

Notes:

ft: feet

ft msl: feet above mean sea level

Groundwater elevation measurements were collected on October 15 and 18, 2010.

The maximum recorded drawdown in the observation wells/piezometers was 0.81 feet in P-4. Piezometer P-4 is located approximately 120 feet west of CGR-8 (**Figure 2**). P-10 and OW-7U are located near the northern and southern property boundaries of the site, respectively. Groundwater levels decreased less than 0.1 foot in P-10 and about one-half of a foot in monitoring well OW-7U. The groundwater level in P-15, located east of the interpreted spring-line fault increased. Review of the hydrograph of P-15 in **Appendix H1** indicates that this increase is the result of regional groundwater level variations or trends.

For the aquifer test, groundwater production from CGR's southern facility stopped at approximately 2 am on October 15, 2010 and restarted at approximately 11:40 am on October 18, 2010. Prior to after these times the obvious effects of groundwater pumping from the CGR southern facility can be seen in the pre- and post- pump test water level data collected in OW-7U and P-4 (**Appendix H1**). These two monitoring locations are relatively close to the southern site boundary. By comparison, the same magnitude of water level fluctuations are not observed in P-10 located on the northern boundary of the site. However, water levels in P-10 do appear to be slightly influenced by pumping in the Cartago area (**Appendix H1**).

Shallow piezometers RP-1 through RP-4 were completed in the very top portion of the Shallow Zone adjacent to the CBS-2,-4,-6, and -9 spring locations. Groundwater levels in all of the RP piezometers show a distinct diurnal fluctuation which is interpreted to be primarily the result of fluctuations in evapotranspiration (ET) rates during daylight and nighttime hours. Although groundwater level fluctuations might also be the result of increased groundwater pumping during the daytime hours in local wells, the fluctuations are very cyclic and the lowest level in the diurnal fluctuations generally occurs in the late afternoon when ET is expected to be highest. Overall, groundwater levels in the RP decreased from approximately 0.01 to 0.2 feet with the greatest decrease being observed in RP-1 **(Appendix F** and **Appendix H1**). RP-1 is the closest RP piezometers to the pumping well CGR-8. It should be noted that the pre- and post-pump test fluctuations of groundwater levels attributed to changes in ET rates in RP-1, RP-2 and RP-4 locations were on the order of 0.1 feet, which is similar to the overall decrease in these piezometers attributed to pumping in CGR-8.

The general Shallow Zone groundwater gradient beneath the site is predominately towards the east. The groundwater potentiometric surface contour map generated using groundwater elevations after approximately 72 hours of pumping in CGR-8 show a cone of depression immediately surrounding CGR-8 **(Figure F-2, Appendix F**).[5] In the immediate vicinity of CGR-8 the gradient is affected by the pumping, but the overall gradient across the site was not significantly changed. The groundwater elevation contour map generated using data collected 24 hours after pumping stopped (**Figure F-3, Appendix F**) shows that the gradient conditions had returned to their pre-test configuration (**Figure F-1, Appendix F**). Approximately 24 hours after the pump was shut off, water levels in the pumping well CGR-8 recovered approximately 98% or, the groundwater level was 0.17 feet lower than pre-pumping water levels (**Table F-1 and F-3, Appendix F**). The one notable difference between the contours shown in **Figures F-1 and F-3** is the significant southeast gradient in the area immediately south of the site. This gradient is the result of production in CGR-2 and CGR-4.

6.6.1.2 Spring Flow and Irrigation Ditch Water Level Measurements

The inserted table below summarizes spring flow readings prior to the start of the pump test and at the end of the pump test, and the change in spring flow rates. Hydrographs for spring flow for the test are presented in **Appendix I1**.

[5] The aerial extent of the cone of depression in some directions is likely an over-estimate based on the interpolation method used by the computer program (SURFER® 8.05).

Summary of Spring Flow Measurements - CGR-8 Aquifer Test

Spring ID	Approx. Distance to Pumping Well (ft)	Spring Flume Flow Before Start of Aquifer Test[1] (gpm)	Spring Flume Flow at End of Aquifer Test[1] (gpm)	Change in Flow Rate (gpm)	Percent Change
ES-1	580	4.41	4.10	-0.31	-7.0%
ES-3A	1,120	93.7*	105.3	+11.6	+12.4%
CBS-2	425	1.27	0.95	-0.32	-25.2%
CBS-4	270	0.95	0.46	-0.50	-52.2%
CBS-6	645	8.12*	7.29	-0.83	-10.2%
CBS-9	1,180	8.56	6.50	-2.05	-24.1%
Site Spring Total		**18.90**	**15.20**	**-3.70**	**-19.6%**
Total Combined Springs		**117.0**	**124.6**	**+7.6**	**+6.5%**

Notes:
ft: feet
gpm: gallons per minute
Site Spring Total : Summation of all monitored site spring flow (CBS-2, 4, 6 and 9)
Total Combined Springs: Summation of all the springs monitored (i.e., springs listed).
[1] : Spring flow measurements collected before start of aquifer test were collected on October 15, 2010 and spring flow measurements at end of test were collected on October 18, 2010.
*: Spring reading collected near beginning of test (approximately 9:00) used for initial spring measurement at these locations.

The spring flow data indicate that:

- Except for ES-3A, all flows at the monitored springs decreased during the pump test. The reduction of spring flow ranged from 0.31 to 2.05 gpm, with the highest reduction occurring in CBS-9.
- Flow in springs CBS-2, CBS-4 and CBS-9 was reduced by the greatest percentage (approximately 25, 52, and 24 percent, respectively) during the aquifer test, but flow recovered in the springs to pre-pumping flow conditions after the test was completed (**Appendix I1**).
- Spring flow at ES-3A increased by approximately 11.6 gpm or 12.4 percent (%) during the test. This is likely due to a stop in nearby groundwater production at the southern facility (from CGR-2 and CGR-4) before start of the aquifer test and the subsequent recovery of the spring flow.
- The total monitored site spring flow (total of flow observed in CBS-2, CBS-4, CBS-6 and CBS-9) was reduced by 19.6% after 72 hours of pumping. The total combined monitored spring flow that includes the off-site springs ES-1 and

ES-3A increased slightly over the test, due to the measured increase in spring flow at ES-3A. The observed overall increase in spring flow is again likely due to a stop in groundwater production at the southern facility (from CGR-2, and CGR-4) before the start of the aquifer test and the subsequent recovery of the spring flow.

- The spring hydrographs (**Appendix I1**) show that most of the springs show a daily, cyclic high and low flow condition. Generally, the spring flow is highest in the mornings and the flow is lowest in the afternoon. This cycle may be the result of changes in ET and possibly an increase of pumping in wells in the area.

Piezometer RP-5 was installed to evaluate the level of water in the main collection ditch. The hydrograph of RP-5 shows daily cyclic fluctuations with the high water elevation recorded in the mornings, and low elevation recorded in the late afternoons which are not attributed to pumping in CGR-8 (**Appendix H1**). Water levels in the main collection ditch did not significantly decrease during the pump test. After 72 hours of pumping in CGR-8 an overall water level elevation change of only -0.02 feet was measured in RP-5.

6.6.1.3 CGR-8 Aquifer Test Analyses

AQTESOLV aquifer analytical results for the CGR-8 aquifer test are presented in **Appendix J1**. The aquifer analytical results are summarized in **Table 4**. Drawdown data collected in wells CGR-9, CGR-10, and Piezometer P-4 during the aquifer test were analyzed using the unconfined Theis solution, and the leaky confined Newman-Witherspoon solution.

Results of the analyses show a fairly consistent range of transmissivity and hydraulic conductivity values (**Table 4**). Estimated transmissivity ranged from 1.3 x 10^4 to 5.2 x 10^4 ft^2/day with an average estimated transmissivity of 3.9 x10^4 ft^2/day. Estimated hydraulic conductivity ranged from 180 to 720 ft/day with an average estimated hydraulic conductivity of 550 ft/day.

6.6.2 Well CGR-9 Aquifer Test

The 72-hour constant rate aquifer test was conducted on Well CG-9 starting on September 17, 2010, at approximately 8:00 am and ending at approximately 9:30 am on September 20, 2010. The well was pumped at approximately 170 gpm. See Section 5.4 more specific details on aquifer test methodology.

6.6.2.1 Groundwater Level Measurements

Tables F-4 through F-6 in **Appendix F** present groundwater level measurements collected prior to pumping, after approximately 72 hours of pumping (end of test), and after 24 hours of recovery. **Figures F-4 through F-6** present shallow groundwater potentiometric surface contours maps for these three monitoring events.

The groundwater elevation hydrographs for wells and piezometers with transducers for the CGR-9 aquifer test (**Appendix H2**) include a week of background data collected both prior to and after the test.[6] Relatively minor drawdown and subsequent was observed in most of the wells and piezometers monitored. Drawdown in the pumping well CGR-9 after 72 hours of pumping was 7.53 feet. The specific capacity of CGR-9, defined as pumping rate divided by drawdown after 72-hours of pumping, was calculated to be 22.6 gpm/ft.

The inserted table below is a summary of water levels in key wells or piezometers measured prior to pumping and after approximately 72 hours of pumping.

Change in Groundwater Elevations in Selected Monitoring Locations - CGR-9 Aquifer Test

Well / Piezometer ID	Distance to Pumping Well	Groundwater Elevation Before Pump Test (ft msl)	Groundwater Elevation at End of 72-Hour Pump Test (ft msl)	Change in Water Elevation (ft)
CGR-8	700	3616.53	3616.08	-0.45
CGR-9	0	3617.68	3610.15	-7.53
CGR-10	530	3618.39	3617.52	-0.87
P-10	2,350	3619.93	3619.84	-0.09
OW-7U	1,020	3616.24	3616.12	-0.12
P-12	230	3617.24	3616.32	-0.92
P-15	530	3603.22	3603.16	-0.06

Notes:

ft: feet

ft msl: feet above mean sea level

Groundwater elevation measurements were collected on September 17 and 20, 2010.

[6] Transducers in piezometer P-2 and P-12 were moved in preparation for the CGR-10 aquifer test and, therefore, a full week of data following the CGR-8 aquifer test was not recorded.

The maximum recorded drawdown in an observation well/piezometer after 72 hours of pumping was 0.92 feet in P-12. Piezometer P-12 is located approximately 230 feet east of CGR-9. Observed drawdown in the southern monitoring location, OW-7U was 0.12 feet and observed drawdown in the northern most monitoring location P-10 was 0.09 feet. Groundwater levels in P-15, the monitoring location east of the Spring-line fault, decreased overall by 0.06 feet. However, based on the review of the P-15 hydrograph in **Appendix H2**, it difficult to distinguish whether the change is the result of regional groundwater variations or pumping in CGR-9.

The hydrographs of wells OW-7U and CGR-8 (**Appendix H2**) show the effects of groundwater pumping from the southern facility in the pre- and post pump test water level data. This is indicated by peaks and valleys on the hydrograph that correspond to pumping cycles at the southern facility. Groundwater production from the southern facility stopped at approximately 6 pm on September 16, 2010 and restarted at approximately 2:30 pm on September 20, 2010.

Groundwater levels in shallow piezometers RP-1 through RP-4 displayed an overall decrease of approximately 0.1 feet over the course of the aquifer test (**Appendix F** and **Appendix H2**). Again, the shallow groundwater levels showed a distinct diurnal fluctuation which is attributed primarily to changes of ET during daylight and night time hours. It should be noted that the pre- and post-pump test fluctuations of groundwater levels in some of the RP locations were on the order of 0.2 feet which is greater than the observed overall decrease attributed to pumping in CGR-9 (approximately 0.1 feet).

The groundwater potentiometric surface contour map (**Figure F-5, Appendix F**) generated using groundwater elevations after approximately 72 hours of pumping in CGR-9 show a cone of depression surrounding CGR-9.[7] In the immediate vicinity of CGR-9 the gradient is affected by the pumping, but in general the overall gradient across the site remains eastward. The groundwater elevation contour map generated using data collected 24 hours after pumping ended in CGR-9 (**Figure F-6, Appendix F**) shows that the gradient beneath the site is generally the same as pre-pumping conditions (**Figure F-4, Appendix F**) and the cone of depression is not present. Approximately 24 hours after the pump was shut off, the CGR-9 water level had recovered approximately 97% or, the groundwater level was 0.20 feet lower than pre-pumping water levels.

6.6.2.2 Spring Flow and Irrigation Ditch Water Level Measurements

[7] The aerial extent of the cone of depression in some directions is likely an over-estimation due to interpolation method of the computer contouring program.

The inserted table below summarizes spring flow readings prior to the start of the pump test and at the end of the pump test, and the change in flow rates. Hydrographs of spring flow for the test are presented in **Appendix I2**.

Summary of Spring Flow Measurements - CGR-9 Aquifer Test

Spring ID	Approx. Distance to Pumping Well (ft)	Spring Flume Flow Before the Aquifer Test[1] (gpm)	Spring Flume Flow at End of 72-Hour Aquifer Test[1] (gpm)	Change in Flow Rate (gpm)	Percent Change
ES-1	1,300	5.06	5.06	0.00	0.0%
ES-3A	1,820	98.3*	96.0	-2.2	-2.2%
CBS-2	480	1.10	0.81	-0.29	-26.4%
CBS-4	755	0.95	0.56	-0.39	-41.1%
CBS-6	258	5.76	4.74	-1.02	-17.7%
CBS-9	520	9.00	5.06	-3.94	-43.8%
Site Spring Total		**16.81**	**11.17**	**-5.64**	**-33.6%**
Total Combined Spring		**120.0**	**112.2**	**-7.8**	**-6.5%**

Notes:
ft: feet
gpm: gallons per minute
Site Spring Total: Summation of monitored site spring flow (CBS-2, 4, 6 and 9)
Total Combined Spring : Summation of all the springs monitored (i.e., listed).
[1] : Spring flow measurements collected before start of aquifer test were collected on October 15, 2010 and spring flow measurements at end of test were collected on October 18, 2010.
*: Spring reading for ES-3A collected near beginning of the test (8:14) used for initial spring flow measurement.

The spring flow data indicate:

- With the exception of spring flow in ES-1, spring flows at all the monitored springs locations decreased. The reduction in spring flow ranged from 0.29 gpm to 3.94 gpm, with the highest reduction measured at CBS-9. Flow was reduced in CBS-9 by 43.8%.
- The total monitored site spring flow (total of flow observed in CBS-2, CBS-4, CBS-6 and CBS-9) was reduced by 5.64 gpm or 33.6% after 72 hours of pumping. The total combined monitored spring flow, that includes flows at

off-site springs ES-1 and ES-3A, was reduced by a total 7.8 gpm or 6.5% during the aquifer test.

- The spring hydrographs (**Appendix I2**) show that most of the springs display a daily, cyclic high and low flow condition. Generally, the spring flow is highest in the mornings and lowest in the afternoons.

RP-5 monitors surface water levels in the main collection ditch. The hydrograph of RP-5 shows daily cyclic fluctuations on the order of magnitude of 0.02 to 0.05 feet per day with the high water elevation recorded in the mornings, and low elevation recorded in the late afternoon. The overall water level of the irrigation ditch did not change significantly during the aquifer test. After 72 hours of pumping in CGR-9 a water level elevation change of only -0.01 feet was measured.

6.6.2.3 CGR-9 Aquifer Test Analyses

AQTESOLV aquifer analytical results for the CGR-9 aquifer test are presented in **Appendix J-2**. The aquifer analytical results are summarized in **Table 5**. Drawdown data collected in wells CGR-8, CGR-10, and piezometers P-2 and P-12 during the test were analyzed using the unconfined Theis solution, and the leaky confined Newman-Witherspoon solution.

Results of the aquifer test analyses show a fairly consistent range of transmissivity and hydraulic conductivity values (**Table 5**). Estimated transmissivity ranged from 1.2×10^4 to 3.1×10^4 ft^2/day with an average estimated transmissivity of 3.9×10^3 ft^2/day. Estimated hydraulic conductivity ranged from 55 to 430 ft/day with an average estimated hydraulic conductivity of 230 ft/day.

6.6.3 Well CGR-10 Aquifer Test

The 72-hour constant rate test was conducted on well CGR-10 starting on November 12, 2010, at approximately 9:00 am and ending at approximately 9:00 am on November 15, 2010. The well was pumped at approximately 170 gpm. See Section 5.4 more specific details on aquifer test methodology.

6.6.3.1 Groundwater Level Measurements

Tables F-7 through F-9 in **Appendix F** present groundwater level measurements collected immediately prior to pumping, after approximately 72 hours of pumping (end of test), and after 24-hours of recovery. **Figures F-7 through F-9 in Appendix F** present shallow groundwater potentiometric surface contours for these three monitoring events.

The groundwater elevation hydrographs for wells and piezometers with transducers for the CGR-10 pump test (**Appendix H3**) present a week of background data prior to the test, and a week after the test. Relatively minor drawdown and subsequent was observed in most of the wells and piezometers monitored.

The inserted table below is a summary of key wells or piezometers measured prior to pumping and after approximately 72 hours of pumping.

Changes in Groundwater Elevations in Selected Monitoring Locations - CGR-10 Aquifer Test

Well / Piezometer ID	Distance to Pumping Well (ft)	Groundwater Elevation Before Pump Test (ft msl)	Groundwater Elevation at End of 72-Hour Pump Test (ft msl)	Change in Groundwater Elevation (ft)
CGR-8	1,230	3616.90	3616.76	-0.14
CGR-9	530	3617.90	3617.06	-0.84
CGR-10	0	3618.63	3610.50	-8.13
P-10	1,830	3620.02	3619.81	-0.21
OW-7U	1,540	3616.60	3616.62	0.02
P-11	210	3618.16	3617.09	-1.07
P-15	780	3605.63	3605.70	0.07

Note:
ft: feet
ft msl: feet above mean sea level
Groundwater elevation measurements were collected on November 12 and 15, 2010.

The drawdown in the pumping well CGR-10 was measured at 8.13 feet after 72 hours of pumping. The specific capacity of CGR-10, defined as pumping rate divided by drawdown after 72hours of pumping, was calculated to be 20.9 gpm/ft. The maximum drawdown measured in an observation well after 72 hours of pumping was 1.07 feet recorded in P-11. P-11 is located approximately 210 feet northeast of CGR-10. Minor fluctuations of water levels in wells P-10 and OW-7U, located near the northern and southern property boundaries of the site, were observed. Groundwater levels decreased 0.21 feet P-10. Groundwater levels in OW-7U initially decreased about 0.04 feet in OW-7U (**Appendix H3**) and then began to gradually increase. This observation is likely due to groundwater levels recovering from the cessation of pumping in the southern production well CGR-2 and CGR-4. Overall groundwater levels increased 0.02 feet in OW-7U during the test. The groundwater level in P-15, located east of the interpreted

Spring-line fault increased. Review of the hydrograph of P-15 in **Appendix H3** indicates that this observed increase is the result of regional groundwater level variations.

The hydrographs of wells OW-7U and CGR-8 show obvious effects of groundwater pumping from the southern facility in the pre- and post-pump test water level data (**Appendix H3**). This is indicated by peaks and valleys on the hydrograph that correspond to pumping cycles at the southern facility. Groundwater production from the southern facility stopped at approximately 2 am on November 12, 2010 and restarted at approximately 11:30am on November 15, 2010.

Shallow piezometers RP-1 through RP-4 displayed slight to no water level fluctuations during the course of the pump test (**Appendix H3**). The greatest drawdown (approximately 0.17 feet) was observed in piezometer RP-4. As observed in previous tests, the groundwater levels in the shallow RP piezometers show the diurnal fluctuations interpreted to be primarily due to fluctuations in ET during daylight and night time hours, although the magnitude of the fluctuations is less than 0.1 feet and is not as great as previously observed in the CGR-8 and CGR-9 tests. This is likely due to the lower ET rates in November compared to September and October when the CGR-8 and CGR-9 tests were conducted.

RP-5 monitors surface water levels in the main collection ditch. The hydrograph of RP-5 also shows daily cyclic fluctuations with the high water elevation recorded in the mornings, and low elevation recorded in the late afternoon. The overall water level of the irrigation ditch did not change significantly during the aquifer test. After 72 hours of pumping in CGR-10 an overall water level elevation change of only -0.02 feet was measured at RP-5.

The general groundwater gradient in November 2010 was toward the east (**Figures F-7 through F-9, Appendix F**). The potentiometric surface contour map generated using groundwater elevations after approximately 72 hours of pumping in CGR-10 show a cone of depression surrounding CGR-10 (**Figure F-8, Appendix F**).[8] In the immediate vicinity of CGR-10 the gradient is affected by the pumping, but in general the eastward gradient across the site appears to be unaffected. The contour map generated using data collected 24 hours after pumping (**Figure F-9, Appendix F**) shows that the gradient is similar to pre-test conditions and the cone of depression is not present. Approximately 24 hours after the pump was shut off, the groundwater level in the pumping well CGR-10 had recovered approximately 98% or, the groundwater level was 0.18 feet lower than pre-

[8] The aerial extent of the cone of depression is likely an over-estimate in some directions based due to the interpolation method used by the computer contouring program.

pumping water levels. The one notable difference between the contours shown in **Figures F-7 and F-9** is the significant southeast gradient in the area immediately south of the site. This gradient is the result of production in CGR-2 and CGR-4.

6.6.3.2 Spring Flow and Irrigation Ditch Water Level Measurements

The inserted table below summarizes spring flow readings prior to the start of the pump test and at the end of the pump test, and the overall change in flow rates. Hydrographs for spring flow for the test are presented in **Appendix I1**.

Summary of Spring Flow Measurements - CGR-10 Aquifer Test

Spring ID	Approx. Distance to Pumping Well (ft)	Spring Flume Flow Before the Aquifer Test (gpm)	Spring Flume Flow at End of 72-Hour Aquifer Test (gpm)	Change in Flow Rate (gpm)	Percent Change
ES-1	1,830	7.29	8.12	+0.83	+11.4%
ES-3A	2,420	105.3	110.2	+4.9	+4.6 %
CBS-2	960	2.03	1.44	-0.59	-29.1%
CBS-4	1,260	1.63	1.63	0.00	0.0%
CBS-6	675	10.89	8.12	-2.77	-25.4%
CBS-9	252	9.00	4.73	-4.27	-47.4%
Site Spring Total		**23.35**	**15.92**	**-7.63**	**-32.4%**
Total Combined Spring		**136.1**	**134.2**	**-1.9**	**-1.4%**

ft: feet

gpm: gallons per minute

Site Spring Total: Summation of monitored site spring flow (CBS-2, CBS-4, CBS-6 and CBS-9)

Total Combined Spring : Summation of all the springs monitored (i.e. all listed springs)

Note: Spring flow measurements were collected on November 12, 2010 (before test) and November 15, 2010 (end of test).

The spring flow data indicate:

- Spring flows were reduced at springs CBS-2, CBS-6 and CBS-9. The reduction of spring flow ranged from 0.59 gpm to 4.27 gpm, with the highest reduction occurring in the spring located nearest the pumping well, CBS-9. The total monitored site spring flow (total of flow observed in CBS-2, CBS-4, CBS-6 and CBS-9) was reduced by 7.63 gpm or 32.4% after 72 hours of pumping at 170 gpm.

- The total combined spring flow decreased by 1.4% or by about 1.9 gpm. The fact that the decrease in monitored site spring flow (-7.63 gpm) was greater than the decrease in total combined spring flow (-1.9 gpm) is due to spring flow increasing at the ES-1 and ES-3A spring locations. The observed increase in spring flow at ES-1 and ES-3A is likely due to a stop in groundwater production at the southern facility (from CGR-2 and CGR-4) before the start of the aquifer test and the subsequent recovery of the spring flow in these locations.

6.6.3.3 CGR-10 Aquifer Test Analyses

AQTESOLV aquifer analytical results for the CGR-10 aquifer test are presented in **Appendix J3**. The aquifer analytical results are summarized in **Table 6**. Drawdown data collected in wells CGR-8, CGR-9, and piezometers P-5 and P-11 during the test analyzed using the unconfined Theis solution and the leaky confined Newman-Witherspoon solution were used.

Estimated transmissivity ranged from 6.6 $x10^3$ to 5.2 $x10^4$ ft^2/day with an estimated average transmissivity of 2.0 $x10^4$ ft^2/day (**Table 6**). Estimated hydraulic conductivity ranged from 92 to 720 ft/day with an estimated average hydraulic conductivity of 280 ft/day.

6.7 Water Sample Analytical Results

The following sections present the salient results of groundwater and spring sampling results. Groundwater samples were collected at the end of each aquifer test and analyzed using methodology required for the State of California private water source operator license. The laboratory results, including a summary sheet and laboratory reports, are presented in **Appendix K**.

6.7.1 CGR-8 Laboratory Results

The laboratory analytical results for CGR-8 groundwater samples are presented in **Appendix K**. The following are the salient findings of the results:

- There were no laboratory analytical results that exceeded the federal Environmental Protection Agency (EPA) or State of California Maximum Contaminant Levels (MCLs)[9] for drinking water.

[9] Based on the U.S. EPA Maximum Contaminant Level list updated on November 28, 2008.

- General water quality results indicate excellent water quality. The total dissolved solid (TDS) concentration was reported at 145 milligrams per liter (mg/L). The major cations, calcium and sodium, were measured at concentrations of 21.3 mg/L and 19.8 mg/L, respectively. The major anions, bicarbonate and sulfate, were measured at concentrations of 75.3 mg/L and 18.6 mg/L, respectively.
- The primary inorganic compounds detected were arsenic, barium, and fluoride, at concentrations of 0.0095 mg/L, 0.016 mg/L, and 0.69 mg/L, respectively.
- Color, odor and turbidity were not detected, and total Coliform and E. coli were reported as absent.
- Organic compounds analyzed using EPA Method 524.2, EPA 504.1, EPA 508.1, EPA 515.3, EPA 525.2, EPA 531.1, EPA 547, EPA 548.1, EPA 549.2, EPA 549.2, EPA 1613, and EPA 314.0 were not detected above the laboratory reporting limit.

6.7.2 CGR-9 Laboratory Results

The laboratory analytical results for CGR-9 are presented in **Appendix K**. The following are the salient findings of the results:

- There were no laboratory analytical results that exceeded the federal or State of California MCLs for drinking water.
- General water quality results indicate excellent water quality. The total dissolved solid concentration was 135 mg/L. The major cations, calcium and sodium, were measured at concentrations of 16.1 mg/L and 15.9 mg/L, respectively. The major anions, bicarbonate and sulfate, were measured at concentrations of 68.1 mg/L and 12.8 mg/L, respectively.
- The primary inorganic compounds detected were barium, fluoride, and nitrate at concentrations of 0.019 mg/L, 0.74 mg/L, and 0.19 mg/L, respectively.
- Color, odor and turbidity were not detected, and total Coliform and E. coli were reported as absent.
- Organic compounds analyzed using EPA Method 524.2, EPA 504.1, EPA 508.1, EPA 515.3, EPA 525.2, EPA 531.1, EPA 547, EPA 548.1, EPA 549.2, EPA 549.2, EPA 1613, and EPA 314.0 were not detected above the laboratory reporting limit.

6.7.3 CGR-10 Laboratory Results

The laboratory analytical results for CGR-10 are presented in **Appendix K3**. The following are the salient findings of the results:

- There were no laboratory analytical results that exceeded the federal or State of California MCLs for drinking water.
- General water quality results indicate excellent water quality. The total dissolved solid concentration was 121 mg/L. The major cations, calcium and sodium, were measured at concentrations of 18.3 mg/L and 17.5 mg/L, respectively. The major anions, bicarbonate and sulfate, were measured at concentrations of 68.3 mg/L and 14.4 mg/L, respectively.
- The primary inorganic compounds detected were barium, fluoride, and nitrate at concentrations of 0.020 mg/L, 0.73 mg/L, and 0.16 mg/L, respectively.
- Color, odor and turbidity were not detected, and total Coliform and E. coli were reported as absent.
- Organic compounds analyzed using EPA Method 524.2, EPA 504.1, EPA 508.1, EPA 515.3, EPA 525.2, EPA 531.1, EPA 547, EPA 548.1, EPA 549.2, EPA 549.2, EPA 1613, and EPA 314.0 were not detected above the laboratory reporting limit.

7.0 HYDROGEOLOGIC SITE CONCEPTUAL MODEL

A hydrogeological site conceptual model (SCM), based on the information collected during this investigation and past investigations, is presented in this section. The SCM was used to develop a three dimensional groundwater flow model for the site (Section 8.0).

The site is located in the southern portion of the Owens Valley Groundwater Basin (DWR, 2003). The basin occupies a structural valley that, in the vicinity of the site, is bounded on the west by the granitic bedrock of the Sierra Nevada Mountains and on the east by the sedimentary bedrock of the Inyo Mountains. The major groundwater bearing unit in the basin is a thick sequence of alluvium that has been derived from erosion of bedrock in the bordering mountain areas. The alluvium beneath the site is principally derived from the Sierra Nevada Mountains to the west and generally consists of sands and gravels. These alluvial sands and gravels are interbedded or interfingered with finer-grained lacustrine deposits (i.e., lake deposits).

The interfingered relationship of the alluvium and lacustrine deposits beneath the site is generally depicted in the site cross-section A-A' (**Figure 5**) and **Figure A-1 in Appendix A.** The observed sequence of lacustrine and alluvial sediments beneath the site is the result of deposition associated with ancient fluctuations of water levels in Owens Lake. Alluvial materials derived from the Sierra Nevada Mountains were deposited along the shoreline while fine-grained lacustrine materials were deposited in the shallow lake waters. As the elevation of the lake varied, the shoreline moved laterally, causing interfingering of the coarse alluvial materials and the fine-grained lake deposits. The lacustrine deposits generally consist of silts, clays and very fine sands, and have a relatively high organic content. A fine-grained layer encountered at a depth of approximately 80 feet across the southern portion of the site during investigative drilling is interpreted to be a lacustrine deposit. The sequence of alluvium and lacustrine deposits beneath the site is at least 750 feet thick (JMM, 1993). Based on site drilling logs, the percentage of fine-grained material (lacustrine deposits) increases to the east.

Groundwater beneath the site is mostly derived from precipitation (rainfall) and snowmelt in the Sierra Nevada Mountains to the west that runs off and infiltrates the alluvium near the mountain base. Much of the groundwater recharge for the site is thought to occur along Cartago Creek and Braley Creek where surface water runs off the mountains onto the alluvial fans that border the mountain's eastern face. Surface water or runoff quickly percolates into the sandy and gravelly alluvium and moves downward to the groundwater table. Some groundwater recharge also may occur from underflow through bedrock fractures and from direct precipitation on the valley floor.

Groundwater in the alluvium flows eastward, away from the Sierra Nevada Mountains and towards the central portion of the basin. Groundwater beneath the site occurs under unconfined conditions, although where fine-grained layers are present, local semi-confined conditions may occur. The upper aquifer material beneath the site is referred to as the Shallow Zone. The Shallow Zone is defined herein as the saturated sand and gravel aquifer that overlies the fine-grained lacustrine layer that occurs at a depth of approximately 80 feet. The 80-foot fine-grained layer is considered to be an aquitard that separates the Shallow Zone from deeper sandy and gravely alluvium. Based on aquifer tests performed by previous investigators, there is some hydraulic connection between the Shallow Zone and the deeper portions of the alluvial aquifer beneath the Shallow Zone. All test wells and piezometers installed during this investigation are completed in the Shallow Zone.

The depth to the shallow groundwater table beneath the site gradually decreases towards the east. In the south central portion of the site shallow groundwater intersects the ground surface along an approximate line where springs and seeps are observed. This line is interpreted to be associated with the presence of a fault called the Spring-line fault. The rise of groundwater may also be associated with the increase of fine-grained lacustrine deposits towards the east, although the linear nature of the spring locations suggests a fault. Both the Spring-line fault and/or the increase of fine-grained deposits are interpreted to impede groundwater flow which subsequently produces a rise of the groundwater table, and the observed springs and meadowlands in the central and eastern portions of the site. The source of spring water surfacing on the site is the Shallow Zone.

Parallel and immediately east of the spring lineament is a man made water collection ditch (the main collection ditch) that is approximately 3 to 6 feet deep and 2,000 feet long. Currently, the main collection ditch is kept full of water from groundwater discharging directly into the ditch from the bottom and sidewalls of the ditch (i.e., groundwater seeping into the ditch) and the lineament of springs and seeps that flow into the ditch. Water in the collection ditch ultimately flows out into the eastern meadow lands.

8.0 GROUNDWATER FLOW MODELING

A groundwater model was constructed to simulate the salient features of the groundwater flow field, including pumping wells, springs, hydraulic barriers and sources of recharge to simulate the environmental response to proposed future groundwater pumping from wells at the site. This section provides a brief summary of the model structure and simulation results. Refer to **Appendix L** for a more detailed discussion of the model development and operation. Groundwater flow was simulated using MODFLOW (USGS) through the graphical user interface Groundwater Modeling System (GMS) 7.0 from Aquaveo. Model development and calibration was conducted for the purpose of evaluating the potential long-term effects of future pumping scenarios on spring flow and groundwater levels. In regards to groundwater levels, primary importance was applied to determining the effects on groundwater levels at the northern and southern boundaries of the site.

A variety of information and data were used in developing the model. The lithology of the site area was simulated using simplified site stratigraphy consisting of:

- Layer 1 - The upper sandy alluvial layer (Shallow Zone).
- Layer 2 - The fine-grained layer (lacustrine deposit) first occurring at a depth of approximately 80 feet across the site.
- Layer 3 - The sandy alluvial layer occurring below the 80-foot fine-grained layer.

The model also simulated the Spring-line fault, springs, ET, pumping wells, and observation wells. The fault was modeled as a hydraulic flow barrier, which reduces the flow conductance through the model, beginning at the surface and extending through the domain vertically. The springs were modeled as drains which remove groundwater from between zero and two feet below the ground surface and discharge them from the domain (do not return to groundwater).

Initial input values (hydraulic conductivity, ET, hydraulic barrier conductivity, drain conductance) were based on professional judgment, using typical values for the site conditions, except for the hydraulic conductivity of the upper layer or Shallow Zone, which was based on the results of well testing during this investigation (**Tables 4 through 6**). After model construction, the model was calibrated by adjusting input values within an acceptable range in order to achieve a good fit between observed and simulated groundwater head and spring flow data. The calibrated value for maximum ET rate was 0.01 feet per day (3.65 feet per year). This ET rate is consistent with an ET rate of 3.2 ft/year estimated by Duell (1988) for meadows in the Owens Valley and is within the range of previously published ET rates for the Owens Valley as presented in the JMM

1993 for the site. The ET rates reported by JMM range from 2.6 ft/year (empirical method where groundwater is less than 8 feet bgs) published by Williams in 1969 to 4.4 ft/year (open water or mudflats) published by Danskin in 1988 (as cited by JMM., 1993).

The existing production and domestic wells at the CGR southern facility, CGR-2, CGR-7, CGR-3, and CGR-4, were simulated at a combined rate of 300 AFY with production distributed at 70%, 20%, 5%, and 5%, respectively, to each well based on personal communications with CGR to create a "base case" of representative historical pumping at the southern facility. Pumping in the town of Cartago located about 1/3 mile from the closest test well CGR-10 and spring (CBS-9) was not explicitly simulated in the model because a good portion of the pumping in this area is thought to be from the deeper zone and relative changes to shallow groundwater levels at the site from this pumping are expected to be small. The base case is a representation of current conditions at the site including current pumping and current spring discharge.

The proposed future pumping expected to occur in wells CGR-8, CGR-9, CGR-10, and CGR-D (proposed future domestic well) was simulated. The future pumping was modeled using four scenarios where the pumping volume in each of the scenarios was distributed as follows: CGR-8-30%, CGR-9-30%, CGR-10-30%, and CGR-D-10%. The four scenarios are:

- Scenario 1: One operating production line using a total of 90 AFY of groundwater. In the model wells CGR-8, CGR-9 and CGR-10 were pumped at constant rate of 16.75 gpm and CGR-D was pumped at a constant rate of 5.6 gpm.
- Scenario 2: Two operating production lines using a total of 180 AFY of groundwater. In the model wells CGR-8, CGR-9 and CGR-10 were pumped at constant rate of 33.5 gpm and CGR-D was pumped at a constant rate of 11.2 gpm.
- Scenario 3: Three operating production lines using a total of 270 AFY of groundwater. In the model wells CGR-8, CGR-9 and CGR-10 were pumped at constant rate of 50.25 gpm and CGR-D was pumped at a constant rate of 16.8 gpm.
- Scenario 4: Four operating production lines using a total of 360 AFY of groundwater. In the model wells CGR-8, CGR-9 and CGR-10 were pumped at constant rate of 67 gpm and CGR-D was pumped at a constant rate of 22.4 gpm.

The 360 AFY groundwater use (Scenario 4) is the maximum amount of water use projected for the project. The model simulated steady state conditions, that is, the pumping was simulated until groundwater levels did not change.

The model scenarios were analyzed to determine the relative changes to: (1) total spring flow discharge; and, (2) water levels in wells located adjacent to the northern and southern boundaries of the site. In the base case (current condition), the model simulated a total spring flow (which is assumed to include water flowing to the main collector ditch) of 433 gpm. This value is consistent with observed discharge (about 350 gpm) from the main collection ditch (see section 6.1) which is considered a minimum discharge estimate.

The model results for the four future pumping scenarios listed above predict that the total spring flow will be decreased by 4.4% for each 90 AFY of pumping. In Scenario 4 (highest proposed pumping rate of 360 AFY), the total spring flow discharge is predicted to be 358 gpm, or a reduction of approximately 17.6% from the base case. Groundwater levels in Scenario 4 are predicted to be approximately 0.2 ft lower in well P-10 located adjacent to the northern boundary of the site and 0.4 ft lower in well OW-7U located adjacent to the southern boundary of the site (**Figure 2**).

9.0 SALIENT FINDINGS AND CONCLUSIONS

CGR currently operates a spring water bottling facility in Olancha, California and is proposing to expand the facility at a site located immediately north of the current facility. The new site is locally referred to as the Cabin Bar Ranch and was used in the past for cattle ranching operations. Natural springs occur along a lineament on the Cabin Bar Ranch site and are proposed to be used to license any new site water sources as bottled spring water.

Groundwater beneath the site occurs in sandy and gravelly alluvium that is interbedded with layers of fine-grained lacustrine (silt, clay, and very fine sand) deposits. The upper approximately 70 to 75 feet of saturated alluvium is referred to as the Shallow Zone. Groundwater in the Shallow Zone generally occurs under unconfined conditions, although where fine-grained layers are present, local semi-confined and leaky conditions may occur. The lineament of natural springs that occurs on the site is interpreted to be the result of a slight rise of groundwater associated with the presence of a fault called the Spring-line fault and possibly the increase of fine-grained lacustrine deposits towards the east. Both the fault and/or the increase of fine-grained deposits act as an impediment to groundwater flow which subsequently produces a rise of groundwater table and the intersection of the groundwater table with the site surface. The groundwater in the Shallow Zone is the source of water that surfaces at the springs.

The principal watershed for the site is the Sierra Nevada Mountains to the west. The primary recharge area for the shallow groundwater beneath the site is the alluvial fans that border the mountain range. Water runs off the mountains during period of snowmelt and rainfall and percolates into the permeable sandy and gravelly alluvial material. Both the watershed and recharge area west of the site are relatively undeveloped. Once the groundwater encounters the groundwater table it then flows eastward towards the central portion of the basin. The shallow groundwater flow direction across the site is towards the east and the gradient is estimated at approximately 0.015 in the central portion of the site.

As part of this investigation, three test wells were installed in the Shallow Zone and aquifer tests were performed on them. A seventy-two hour aquifer test was performed on each test well. The wells were pumped at 170 gpm. During the aquifer tests, groundwater levels in wells and piezometers were monitored including wells located near the northern and southern boundaries of the site. Spring flow at representative spring locations along the spring lineament, including the largest springs, were monitored with flumes. Four site springs (CBS-2, CBS-4, CBS-6 and CBS-9) and two off-site springs (ES-1 and ES-3A) were monitored. The largest site springs are CBS-6 and CBS-9 which

have a base flow of approximately 6 to 10 gpm each in non-pumping conditions. Springs CBS-2 and CBS-4 had a measured flow of approximately 1-2 gpm in non-pumping conditions. Spring ES-3A, located south of the site, is the largest of all the springs and has a flow of approximately 100 gpm in non-pumping conditions. A summary of salient aquifer test results are as follows:

- The specific capacity of the wells after 72 hours of pumping ranged between 19.1 gpm/ft to 22.6 gpm/ft.
- Estimates of average transmissivity of the Shallow Zone ranged between 1.6×10^4 to 3.9×10^4 ft^2/day. This range of transmissivity is relatively high and indicates a relatively high groundwater producing formation.
- Estimates of average hydraulic conductivity of the Shallow Zone ranged between 230 to 550 ft/day.
- After 72 hours of pumping in each of the three tests performed, the observed drawdown in the observation well located adjacent to the site's southern boundary (well OW-7U) ranged between 0.04 feet and 0.55 feet. The greatest drawdown in OW-7U was observed during the CGR-8 test. CGR-8 is the test well located closest to the site's southern boundary and OW-7U.
- After 72 hours of pumping in each of the three tests performed, the observed drawdown in the observation well located adjacent the site's northern boundary (piezometer P-10) ranged between 0.06 feet and 0.21 feet. The greatest drawdown in P-10 was observed during the CGR-10 test. CGR-10 is the test well located closest to the site's northern boundary and P-10.
- Very little to no drawdown was observed in a shallow piezometer (P-15) located east of the Spring-line fault during the three aquifer tests.
- Review of potentiometric surface contour maps prepared for groundwater level monitoring events conducted immediately before the start of each aquifer test, at the end of each aquifer test, and 24 hours after the end of each aquifer test indicates: (1) the eastward gradient across the site was maintained during pumping except for the area in the immediate vicinity of the pumping wells where a cone of depression developed, and (2) the gradient after 24 hours of pumping is similar to pre-test conditions.
- Site spring flow was monitored at four onsite locations during the aquifer tests (locations CBS-2, CBS-4, CBS-6 and CBS-9) and at two locations on the property south of the site (ES-1 and ES-3A). The monitored spring locations are generally evenly distributed along the spring lineament. The highest spring flow

reduction during the three tests all occurred at spring CBS-9 which is the northernmost spring on the site. Reduction of spring flow at CBS-9 ranged between 2.06 gpm and 4.27 gpm from a pre-test flow of 8.5 to 9 gpm. The highest reduction in CBS-9 was observed during the CGR-10 test which is located approximately 250 feet west of the spring. The range of observed flow reduction in the other site springs, CBS-2, CBS-4 and CBS-6 were 0.29 to 0.59 gpm, 0 to 0.49 gpm, and 0.83 to 2.77 gpm, respectively. Percentage-wise these reductions together represent a 20% to 34% reduction in total monitored site spring flow after 72 hours of pumping at 170 gpm in site test wells.

- During the three aquifer tests, the change in observed flow reduction in the off-site springs ES-1 and ES-3A ranged between -0.31 to + 0.83 gpm and -2.2 gpm to +11.6 gpm, respectively. Spring flow in ES-1 and ES-3A during the CGR-8 and CCG-10 tests either did not change or actually increased, probably as a result of the cessation of pumping of nearby offsite wells CGR-2 and CGR-4 which were turned off approximately 6 hours before the start of these tests. As a consequence, an increase in total combined spring flow (flow in all six springs monitored) was observed during the CGR-8 test and a slight 1.4% decrease (-1.9 gpm) was observed during the CGR-10 test. Some small or more moderate reduction in total spring flow would have likely been observed during these aquifer tests if recovery were more complete (and the offsite wells did not interfere). For example, total monitored spring flow was reduced by 7.8 gpm or 6.5% during the CGR-9 test when the pre-test recovery period was approximately 14 hours.

Groundwater sampling results indicate that water quality is excellent. The TDS concentration of the water in the three test wells ranged from 121 mg/L to 145 mg/L. There were no laboratory analytical results that exceeded the federal or State of California MCLs for drinking water.

A three-dimensional groundwater model with a MODFLOW platform was completed to predict the long-term relative changes to total spring flow discharge and long-term changes in groundwater levels in areas north and south of the site. In the base case, the model simulated a total spring flow (which is assumed to include water flowing to the main collection ditch) of 433 gpm. This is consistent with field observations of discharge from the main collection ditch. The model also assumed that pumping for bottled water production was evenly distributed among the three test wells and that domestic well pumping was approximately 10% of total groundwater extraction. The model predicts that, at steady state conditions, spring flows are decreased by 4.4% for each 90 AFY of pumping. At a long-term pumping rate of 360 AFY, the total spring flow is predicted to reduce by 17.6% from the base case (current conditions). The predicted reduction in

spring flow is consistent with the observed reduction of spring flow observed during aquifer tests at the site. Between the base case and the 360 AFY pumping scenario, groundwater elevations in well P-10, located adjacent to the site's northern boundary, decreased a total of 0.2 feet. Shallow groundwater level decreases further north of P-10, in the area of the town of Cartago, would be less than the predicted 0.2 feet at P-10. Between the base case and the 360 AFY pumping scenario, groundwater elevations in well OW-7U, located adjacent to the site's southern boundary, decreased a total 0.4 feet. Predicted shallow groundwater level decreases further south OW-7U, in the vicinity of the current bottling facility, would be less than 0.4 feet. The predicted change in groundwater levels is consistent with the observed changes of groundwater levels observed during the site aquifer tests.

Based on the hydrogeological data obtained during this investigation and on the results of the groundwater modeling, we conclude the following:

1. The shallow groundwater beneath the site, referred to as the Shallow Zone, and the lineament of spring that occur on the site surface provide a unique resource. The Shallow Zone is characterized by very permeable sand and gravels that allow for relatively high yielding shallow wells, and excellent groundwater quality. Due to the occurrence of springs on the site and the relatively large thickness of the Shallow Zone (approximately 70 to 75 feet), this shallow groundwater resource can be safely developed as a bottled spring water source assuming concurrence from the State of California.

2. The proposed project will not have significant effects on groundwater levels beneath developed properties located south and north of the site.

3. The proposed project will produce modest reductions in area spring flow. The modest spring flow reduction will allow for demonstration of a hydraulic connection between the Shallow Zone and the site springs which is mandatory for licensing the source for bottled spring water production under federal and state labeling laws.

(FOR OFFICE USE ONLY)
DISPOSITION OF APPLICATION

☐ APPROVED ☐ DENIED

☐ APPROVED WITH CONDITIONS LISTED:

☐ Minimum _____ ft. seal of annular space (minimum 2 inches) is required and must be witnessed by Inyo County Environmental Health Services.

☐ A concrete pad shall be placed around the well casing that extends at least two feet laterally in all directions from the outside of the well boring and is a minimum of 4 inches thick. The pad must be sloped away from the well casing.

☐ Well driller's log shall be submitted to Inyo County Environmental Health Services within 30 days of completion of the well.

☐ _____

_____

_____

Inyo County Environmental Health Services recommends that an acceptable bacteriological sample be obtained after the well is completed.

C-57 LICENSE NUMBER: #485165
Cash Deposit ☐
Bond Posted ☐

$ 328.00 Fee paid on _____ Receipt No. _____

I hereby agree to comply with all regulations of the Department of Environmental Health Services and with all ordinances and laws of Inyo County and of the State of California pertaining to well construction, repair, modification and destruction at the time of commencement of work.

Miscellaneous Information

A recreational GPS accurate to +/- 45 feet set for Datum NAD27 was used to calculate Latitude, Longitude & Elevation values. The Section, Township, and Range then determined using the TRS program (TRS accuracy is not guaranteed). The TRS program converts Latitude and Longitude to Section, Township, and Range. The NOTICE at the bottom of this heading also applies.

Drilled By: Gregg Drilling

Notes:

Transducers used were InSitu Level Troll 700© datalogging pressure transducer.

Top of casing elevation at CGR-8 is 3626.88 feet above mean sea level .

Depth to water measurements collected on October 15 between 6:45 and 7:54 am.

Depth to water in CGR-8 was 10.29 feet below top of casing.

Depth is measured as feet of water column above the pressure transducer.

ft amsl Feet above mean sea level

Notes:

Transducers used were InSitu Level Troll 700© datalogging pressure transducer.

Top of casing elevation at CGR-9 is 3627.55 feet above mean sea level .

Depth to water measurements collected on October 15 between 6:45 and 7:54 am.

Depth to water in CGR-9 was 9.94 feet below top of casing.

Depth is measured as feet of water column above the pressure transducer.

ft amsl Feet above mean sea level

Notes:

Transducers used were InSitu Level Troll 700© datalogging pressure transducer.

Top of casing elevation at CGR-10 is 3625.42 feet above mean sea level .

Depth to water measurements collected on October 15 between 6:45 and 7:54 am.

Depth to water in CGR-10 was 7.04 feet below top of casing.

Depth is measured as feet of water column above the pressure transducer.

ft amsl Feet above mean sea level

Notes:

Transducers used were InSitu Level Troll 700© datalogging pressure transducer.

Top of casing elevation at P-1 is 3639.57 feet above mean sea level .

Depth to water measurements collected on October 15 between 6:45 and 7:54 am.

Depth to water in P-1 was 21.51 feet below top of casing.

Depth is measured as feet of water column above the pressure transducer.

ft amsl Feet above mean sea level

10/19/2010 9:38	5.12	265.70	3616.67

Notes:

Transducers used were InSitu Level Troll 700© datalogging pressure transducer.

Top of casing elevation at P-4 is 3631.69 feet above mean sea level .

Depth to water measurements collected on October 15 between 6:45 and 7:54 am.

Depth to water in P-4 was 15.01 feet below top of casing.

Depth is measured as feet of water column above the pressure transducer.

ft amsl Feet above mean sea level

Notes:

Transducers used were InSitu Level Troll 700© datalogging pressure transducer.

Top of casing elevation at P-10 is 3640.66 feet above mean sea level .

Depth to water measurements collected on October 15 between 6:45 and 7:54 am.

Depth to water in P-10 was 20.73 feet below top of casing.

Depth is measured as feet of water column above the pressure transducer.

ft amsl Feet above mean sea level

10/25/2010 9:38	5.27	409.76	3605.49

Notes:

Transducers used were InSitu Level Troll 700© datalogging pressure transducer.

Top of casing elevation at P-15 is 3606.98 feet above mean sea level .

Depth to water measurements collected on October 15 between 6:45 and 7:54 am.

Depth to water in P-15 was 1.77 feet below top of casing.

Depth is measured as feet of water column above the pressure transducer.

ft amsl Feet above mean sea level

Notes:

Transducers used were InSitu Level Troll 700© datalogging pressure transducer.

Top of casing elevation at OW-7U is 3624.70 feet above mean sea level .

Depth to water measurements collected on October 15 between 6:45 and 7:54 am.

Depth to water in OW-7U was 12.10 feet below top of casing.

Depth is measured as feet of water column above the pressure transducer.

ft amsl Feet above mean sea level

Notes:

Transducers used were InSitu Level Troll 700© datalogging pressure transducer.

Top of casing elevation at RP-1 is 3616.4 feet above mean sea level .

Depth to water measurements collected on October 15 between 6:45 and 7:54 am.

Depth to water in RP-1 was 1.83 feet below top of casing.

Depth is measured as feet of water column above the pressure transducer.

ft amsl Feet above mean sea level

10/25/2010 9:38	5.34	409.67	3612.83

Notes:

Transducers used were InSitu Level Troll 700© datalogging pressure transducer.

Top of casing elevation at RP-2 is 3614.32 feet above mean sea level .

Depth to water measurements collected on October 15 between 6:45 and 7:54 am.

Depth to water in RP-2 was 1.56 feet below top of casing.

Depth is measured as feet of water column above the pressure transducer.

ft amsl Feet above mean sea level

Notes:

Transducers used were InSitu Level Troll 700© datalogging pressure transducer.

Top of casing elevation at RP-3 is 3617.27 feet above mean sea level .

Depth to water measurements collected on October 15 between 6:45 and 7:54 am.

Depth to water in RP-3 was 4.32 feet below top of casing.

Depth is measured as feet of water column above the pressure transducer.

ft amsl Feet above mean sea level

10/25/2010 9:38	5.49	409.67	3615.12

Notes:

Transducers used were InSitu Level Troll 700© datalogging pressure transducer.

Top of casing elevation at RP-4 is 3617.74 feet above mean sea level .

Depth to water measurements collected on October 15 between 6:45 and 7:54 am.

Depth to water in RP-4 was 2.63 feet below top of casing.

Depth is measured as feet of water column above the pressure transducer.

ft amsl Feet above mean sea level

Notes:

Transducers used were InSitu Level Troll 700© datalogging pressure transducer.

Top of casing elevation at RP-5 is 3611.13 feet above mean sea level .

Depth to water measurements collected on October 15 between 6:45 and 7:54 am.

Depth to water in RP-5 was 0.74 feet below top of casing.

Depth is measured as feet of water column above the pressure transducer.

ft amsl Feet above mean sea level

Notes:

Transducers used were InSitu Level Troll 700© datalogging pressure transducer.

Top of casing elevation at CGR-8 is 3626.88 feet above mean sea level .

Depth to water measurements collected on September 17 between 6:30 - 7:35 am.

Depth to water in CGR-8 was 10.35 feet below top of casing.

Depth is measured as feet of water column above the pressure transducer.

ft amsl Feet above mean sea level

9/27/2010 9:28	19.45	427.82	3617.20

Notes:

Transducers used were InSitu Level Troll 700© datalogging pressure transducer.

Top of casing elevation at CGR-9 is 3627.55 feet above mean sea level .

Depth to water measurements collected on September 17 between 6:30 - 7:35 am.

Depth to water in CGR-9 was 9.87 feet below top of casing.

Depth is measured as feet of water column above the pressure transducer.

ft amsl Feet above mean sea level

Notes:

Transducers used were InSitu Level Troll 700© datalogging pressure transducer.

Top of casing elevation at CGR-10 is 3625.42 feet above mean sea level .

Depth to water measurements collected on September 17 between 6:30 - 7:35 am.

Depth to water in CGR-10 was 7.03 feet below top of casing.

Depth is measured as feet of water column above the pressure transducer.

ft amsl Feet above mean sea level

Notes:

Transducers used were InSitu Level Troll 700© datalogging pressure transducer.

Top of casing elevation at P-2 is 3632.41 feet above mean sea level .

Depth to water measurements collected on September 17 between 6:30 - 7:35 am.

Depth to water in P-2 was 15.15 feet below top of casing.

Depth is measured as feet of water column above the pressure transducer.

ft amsl Feet above mean sea level
